Abstract

Hypertension is a condition where a person experiences an increase in blood pressure above average on a blood pressure check. Based on the JNC-VII criteria applied in Indonesia Hypertension is expressed as blood pressure equal to or more than 140/90 mmHg. This research aims to identify the factors that most influence hypertensive anxiety patients at the General Hospital M.Th. Djaman Sanggau. This research is quantitative research using descriptive analysis research method with *Cross-Sectional* approach. This study using purposive sampling involved 45 samples of hypertensive patients undergoing treatment at the hospital M.Th.Djaman Sanggau. Data analysis using Chi-Square. The result is there was no relationship between age and anxiety levels of hypertension patients $p = 0.246$ ($p > 0.05$), there was no relationship between sex with anxiety levels of hypertension patients $p = 0.495$ ($p > 0.05$), there was a relationship between the level of education and the level of anxiety of patients hypertension $p = 0.011$ ($p < 0.05$). There is a relationship between work with the anxiety level of hypertension patients $p = 0,000$ ($p < 0,05$). There is a significant relationship between the level of knowledge with the level of anxiety of patients with hypertension $p = 0.001$ ($p < 0.05$). Stress is directly related to an increase in blood pressure so that someone needs to do counseling related to his condition to reduce anxiety, and need changes from individuals to change the risk factors for hypertension with healthy lifestyles such as fruit, vegetables, exercise regularly and reduce excessive consumption of calories and fat.

Keywords: hypertension, level of anxiety, patient characteristic

1. Background

The National Health System strives for health development in Indonesia to be directed towards achieving a higher level of health, which enables humans to live more productively both socio-economic. Increased socio-economic status, health services, lifestyle changes, then in Indonesia there is a shift in the pattern of diseases from infectious diseases to non-communicable diseases and is known as the epidemiological transition. The trend of increasing prevalence of non-communicable diseases is hypertension^(1,2). Hypertension has become a significant public health problem in Indonesia and several countries in the world. World health organization (WHO) estimated that one billion suffered hypertension and was predicted to be 1.15 billion cases in 2025. While 80% were retained in the developing country ⁽³⁾.

Hypertension is categorized as the silent disease because the patient does not know he has hypertension before checking his blood pressure. Hypertension is also often referred to as the "silent killer" because a person can suffer from hypertension for years without realizing it until there is damage to vital organs that are quite heavy which can even bring death(4,5). Hypertension can be defined as a condition which is increasing the level of blood pressure from the normal line(6). In Indonesia, the criteria of hypertension followed by The Joint National Committee on prevention, detection, evaluation, and treatment requirements on High Blood Pressure VII (JNC-VII) blood pressure which is more than or equal with 140/90 mmHg is hypertension(2).

Several factors associated with hypertension including; obesity, age, salt intake, cigarettes, coffee, and stress. Stress becomes a crucial point since it could affect on abnormalities of body hormone such as epinephrine(7). Intrinsic factors that can affect a person's level of anxiety include: age, gender, level of education, level of individual knowledge, and work can also affect own anxiety levels(8,9).

Based on preliminary studies conducted on hypertension patients at the M.Th. Djaman Hospital Sanggau District of 10 respondents there were five with a lack of knowledge and four patients with moderate anxiety and six patients with mild anxiety levels. This research needs to be done considering that besides the high incidence of hypertension, patients are also increasingly aware of periodic check-ups at health facilities and making changes to healthy lifestyles such as eating fruits and vegetables, regular and measurable exercise and avoiding excessive consumption of calories and fat.

2. Objective

The research aimed to identify the factors that most influence hypertensive anxiety patients at the General Hospital M.Th. Djaman Sanggau

3. Method

The research design of this study using a cross-sectional to determine factors associated with hypertension. Purposive sampling was conducted to select 45 samples based on the inclusion criteria. The inclusion criteria including a) Hypertension patients without comorbidities diseases including Diabetes Mellitus, Stroke, Heart Diseases, and Kidney Diseases, b) Willingness to participate in this study, c) Patients aged ≥ 19 years, and d) At least have passed a primary school.

Instruments were used to measure the outcomes including Hamilton Rating Scale for Anxiety (HRS-A)(10). The components measured in this HRS-A are feelings of anxiety, tension, fear, sleep disturbances, intelligence disorders, feelings of depression (moody), somatic or physical (muscle) symptoms, somatic or physical (sensory) symptoms, cardiovascular symptoms, respiratory symptoms, gastrointestinal symptoms, urogenital symptoms, autonomic symptoms, and behavior(11,12).

This measuring instrument consists of 14 groups of symptoms; each group has broken down with more specific symptoms. Each symptom group is given a score (score) of 0-4, which means it is a value of 0 if there are no symptoms or complaints, value 1 if symptoms are mild or one of the signs is present, value 2 if symptoms are moderate or half of the symptoms, value 3, if symptoms are severe or more than half of the symptoms are present, and value 4 if symptoms are severe or all of the symptoms are current (13,14).

Test the validity of the questionnaire the level of knowledge carried out by researchers in health facilities by the location of the study to 30 respondents. The results of the validity test of the knowledge variable about the anxiety of hypertensive patients have obtained 20 valid questions with a calculated value of 0.349-0.632. The reliability test results obtained Alpha values for the patient's knowledge of hypertensive patient anxiety by 0.831. So the question instrument in this study is declared reliable because the value of Alpha Cronbach is more than 0.60 (15,16).

4. Results

4.1 Characteristics of hypertensive patients

Table 1 showed that the majority of respondents aged 56-65 years 22 people (48.7%), results also showed that respondents who were male were 16 respondents (35.6%) and women were 29 respondents (64.4%). The majority of respondents' educational backgrounds appear in this study were Primary and secondary education (Elementary, junior high school, Senior High School) with 24 respondents (53.3%). The majority of the working status of respondents in this study did not work with 28 respondents (62.2%). The majority of respondents' knowledge in this study was good with 27 respondents (60%). The results showed that respondents who had no anxiety 15 respondents (33.3%), respondents with mild anxiety level 12 respondents (26.7%), respondents with moderate anxiety level 12 respondents (26.7%) and respondents with severe anxiety levels six respondents (13.3%).

Table 4.1 characteristic of hypertensive patients

	Characteristics of respondents	n	%
Age	26-35 years (early adult)	4	8.4
	36-45 years old (late adult)	3	11
	46-55 years (early elderly)	13	28.8
	56-65 years (late elderly)	22	48.7
	> 65 tahun (elderly)	3	6.6
Gender	Male	16	35.6
	Female	29	64.4
Educational Background	Primary and secondary education (Elementary, junior high school, Senior High School)	24	53.3
	College (University)	21	46.7
Working Status	Work	17	37.8
	Not work	28	62.2
Knowledge	Enough	18	40
	Good	27	60
Level of anxiety	None	15	33.3
	Mild Anxiety	12	26.7
	Moderate Anxiety	12	26.7
	Severe Anxiety	6	13.3

4.2 Relationship between age with anxiety

The relationship between age and anxiety (table 2) shows the majority of respondents aged 56-65 years (late elderly), i.e. 22 respondents (48.9%) consisting of 7 respondents (15.6%) none anxiety, 5 respondents (11.1%) mild anxiety, 6 respondents (13.3%) moderate anxiety, and 4 respondents (8.9%) severe anxiety. The results

indicated there was no significant relationship between age and anxiety of hypertensive patients ($p = 0.246$).

Table 4.2 relation of age with levels of anxiety

No	Category Age Respondents	Category Level Respondents Anxiety				Total	P-Value
		None	Mild Anxiety	Moderate Anxiety	Severe Anxiety		
1.	26 - 35 years	1 (2.2 %)	1 (2.2 %)	2 (4.4 %)	0 (0)	4 (8.9 %)	0.246
2.	36 - 45 years	3 (6.7 %)	0 (0 %)	0 (0 %)	0 (0 %)	3 (6.7 %)	
3.	46 - 55 years	3 (6.7 %)	5 (11.1 %)	4 (8.9 %)	1 (2.2 %)	13 (28.9 %)	
4.	56 - 65 years	7 (15.6 %)	5 (11.1 %)	6 (13.3 %)	4 (8.9 %)	22 (48.9 %)	
5.	> 65 years	1 (2.2 %)	1 (2.2 %)	0 (0 %)	1 (2.2 %)	3 (6.6 %)	
	Total	15 (33.3%)	12 (26.7 %)	12 (26.7%)	6 (13.3 %)	45 (100 %)	

4.3 Relationships gender with anxiety

The relationship between gender and anxiety (table 3) shows the majority of respondents were female 29 respondents (64.4%) consisting of 7 respondents (15.6%) none anxiety, 9 respondents (20%) mild anxiety, 10 respondents (22, 2%) moderate anxiety and 3 respondents (6.7%) severe anxiety. The results indicated that there was no significant relationship between sex and anxiety in hypertensive patients ($p = 0.495$).

Table 4.3 Gender relations with anxiety levels

No	Gender Respondents	Category Level Respondents Anxiety				Total	P-Value
		None	Mild Anxiety	Moderate Anxiety	Moderate Anxiety		
1.	Female	7 (15.6 %)	9 (20 %)	10 (22.2 %)	3 (6.7 %)	29(64.4 %)	0.495
2.	Male	8 (17.8 %)	3 (6.7 %)	2 (4.4 %)	3 (6.7 %)	16(35.6 %)	
	Total	15 (33.3 %)	12 (26.7 %)	12 (26.7 %)	6 (13.3 %)	45(100 %)	

4.4 Relationship educational background with anxiety

The relationship between education and anxiety (table 4) shows the majority of the education background of respondents primary and secondary education 24 respondents (53.3%), consisting of 3 respondents (6.7%) none anxiety, 6 respondents (13.3%) anxiety mild, 9 respondents (20%) moderate anxiety and 6 respondents (13.3%) severe anxiety. The results indicated that there was a significant relationship between education and anxiety in hypertensive patients ($p = 0.011$)

Table 4.4 Relates the level of educational background to anxiety

No	Educational Background	Category Level Respondents Anxiety				Total	P-Value
		None	Mild Anxiety	Moderate Anxiety	Severe Anxiety		
1.	Primary and secondary education	3 (6.7 %)	6 (13.3 %)	9 (20 %)	6 (13.3 %)	24 (53.3 %)	0.011
2.	Collage	12 (26.7 %)	6 (13.3 %)	3 (6.7 %)	0 (0)	21 (46.7 %)	
	Total	15 (33.3 %)	12 (26.7 %)	12 (26.7 %)	6 (13.3 %)	45 (100 %)	

4.5 Relationship working status relationships with anxiety

The relationship between working status and anxiety level (table 5) shows the majority of respondents did not work 31 respondents (68.9%), consisting of 3 respondents (6.7%) none anxiety, 12 respondents (26.7%) mild anxiety, 10 respondents (22.2%) moderate anxiety and 6 respondents (13.3%) severe anxiety. The results indicated that there was a significant relationship between working status and anxiety in hypertensive patients ($p = 0,000$).

Table 4.5 related the working status with anxiety

No	Working Status	Respondent Anxiety Level Category				Total	P-Value
		None	Mild Anxiety	Moderate Anxiety	Severe Anxiety		
1.	Not working	3 (6,7 %)	12 (26,7 %)	10 (22,2 %)	6 (13,3 %)	31 (68,9 %)	0,000
2.	Work	12 (26,7 %)	0 (0)	2 (4,4 %)	0 (0)	14 (31,1 %)	
	Total	15 (33,3 %)	12 (26,7 %)	12 (26,7 %)	6 (13,3 %)	45 (100 %)	

4.6 Relationship knowledge relationship with anxiety

The relationship between knowledge and anxiety (table 6) shows the majority of respondents with good knowledge 27 respondents (60%), consisting of 14 respondents (31.1%) none anxiety, seven respondents (15.6%) mild anxiety, six respondents (13,3%) severe anxiety. The results indicated that there was a significant relationship between knowledge and anxiety of hypertensive patients ($p = 0,000$).

Table 4.6 related to knowledge and anxiety

No	Knowledge	Category level respondents anxiety				Total	P Value
		None	Mild Anxiety	Moderate Anxiety	Severe Anxiety		
1.	Enough	1 (2.2 %)	5 (11.1 %)	6 (13.3 %)	6 (13.3 %)	18 (40 %)	0.020
2.	Good	14 (31.1 %)	7 (15.6 %)	6 (13.3 %)	0 (0)	27 (60 %)	
	Total	33.3 %	26.7 %	26.6 %	13.3	100	

5. DISCUSSION

5.1 Description anxiety respondents hypertension

The anxiety of hypertension patients that most experience anxiety both mild, moderate and severe. It is due to several factors such as knowledge, educational background and lack of information about hypertension in the respondents. Anxiety arises because of something that is not clear or unknown so that feelings that are not calm, worry, or fear arise (8,17). Some studies are in line stating that anxiety is a manifestation of psychological behavior and various behavioral patterns that occur from feelings of anxiety and subjective tension (18,19).

Anxiety is the only psychological factor that affects hypertension. Anxiety or psychosocial stress can increase blood pressure (20,21). Several studies compared the blood pressure of respondents suffering from anxiety with respondents who did not suffer from anxiety, obtained higher blood pressure results in the group of patients with anxiety than those who were not anxious (22,23).

Anxiety and stress can cause stimulation of the sympathetic nervous system, which increases blood frequency, cardiac output, and peripheral vascular resistance (24,25). Sympathetic effects increase blood pressure, but also mental tension (feeling depressed, moody, confused, anxious, pounding, feeling angry, resentment, fear, guilt) can stimulate the kidney glands to release adrenal hormones and accelerate the heart beat faster and stronger, so that blood pressure will increase. If stress lasts long enough, the body tries to make adjustments so that organic abnormalities or pathological changes arise.

5.2 Relationship age and anxiety respondents of hypertensive patients

In this study, it can be concluded that there is no significant relationship between age and anxiety level in hypertension patients with Pearson Correlation values obtained $p = 0.246$ ($p > 0.05$). Most respondents aged 56-65 years who experience anxiety. Some studies similar to the results of this study are in line which shows that there is no relationship with age level (26,27). The results of this study are consistent with the relationship between age and anxiety with a value of $0.267 > 0.05$ so that there is no relationship between age and anxiety (9,28).

Anxiety disorders can occur at all ages, more often in adulthood and most anxiety occurs at the age of 21-45 years (29,30). Age affects a person's psychology, the higher the age, the better the level of one's emotional maturity and ability to deal with various problems. This is because age relates to experience and views of something, the more a person ages, the more mature the process of thinking and acting on something.

5.3 Relationship gender and anxiety of hypertensive patients

In this study resulted that there was no significant relationship between gender with anxiety levels of hypertension patients with Kolmogorov Smirnov $p = 0.495$ ($p > 0.05$). This study occurred in most women experiencing anxiety. The results of this study are consistent with the results of several studies that gender is not related to the level of significance of patients with a significance value of 0.193 for gender (26,27). The results of this study are in line with the results of several studies; there is a relationship between gender and anxiety with the p-value of $0.073 > 0.05$, so the conclusion is that there is no relationship between gender and anxiety (23,31). Factors that influence anxiety include gender, this study states there is no relationship between gender and anxiety, but basically, women tend to have the anxious attitude because women use their feelings more in responding to all forms of change that occur. Hormonal factors also affect stress levels in women because women tend to have hormones that are not stable than men so that women have more emotional qualities than men.

5.4 Relationship educational background and anxiety of hypertensive patients

In this study, it was concluded that there was a significant relationship between the level of educational background and the level of anxiety in hypertensive patients with Kolmogorov Smirnov $p = 0.011$ ($p < 0.05$). Statistical test results showed a significant relationship between the educational background with anxiety in patients with hypertension ($p\text{-value} = 0.000$). In this study most respondents with primary and secondary education level experienced anxiety. The results of this study are in line with the results of several studies that there is a significant relationship between the back of maternal education and the anxiety level (32,33). Education is a factor that can affect the level of anxiety of someone who has hypertension. In addition to formal training,

individuals who experience hypertension can also increase their knowledge through existing media by the times such as books, magazines, posters, leaflets, and the internet related to hypertension.

5.5 Relationship working status and anxiety of hypertensive patients

This study concluded that there was a significant relationship with the anxiety level of patients with hypertension with Kolmogorov Smirnov $p = 0,000$ ($P < 0.05$). In this study most respondents who did not work experienced anxiety. Results of the correlation between working status and anxiety were a visible relationship between the two variables, meaning that respondents who do not work more anxiety than respondents working. Statistical test results that there is a significant relationship between working status with anxiety in patients with hypertension ($p = 0.001$).

The results of this study are the results of several reviews stating that there is a significant relationship between job status and anxiety level $p = 0.016$ ($p < 0.05$) (29,34). The results of this study are in line with the results of several studies on the relationship between work status and anxiety with the results of $p = 0.01 > 0.05$ so the conclusion is the relationship between work and anxiety (9,28).

In research respondents who work less experience anxiety than respondents do not work. Some studies suggest that someone who works in the formal sector has better access to various information, including health (19,35). When linked, someone who works becomes more comfortable to get information about their health and illness, with the information they get can increase their knowledge about hypertension which in turn can reduce anxiety and even eliminate anxiety the disease. Respondents who work tend to have good knowledge and are easier to understand the condition so that they can carry out the necessary coping mechanisms and can minimize their anxiety. In addition, a study also reported that high activity with relaxation progressive muscle was associated with decreasing blood pressure and cholesterol level (36).

5.6 Relationship knowledge and anxiety respondents hypertension

The results of this study concluded that there was a significant relationship between knowledge and anxiety in patients with hypertension. The results of the study that most of the respondents who had experience enough. The results of the correlation test between the level of knowledge with the level of anxiety of the respondents that the relationship is strong and has a definite pattern, meaning that the enough the respondent's knowledge about hypertension will increase the anxiety experienced respondents.

The results of this study are in line with several studies stating that there is a significant relationship between knowledge and situation (29,37). The above is closely related to public awareness about hypertension if individual knowledge about hypertension will motivate patients to participate in modifying lifestyles such as losing weight, reducing alcohol consumption, regular exercise and increased consumption of fruits and vegetables.

6. CONCLUSION

Majority of respondents aged 56-65 years 22 people (48.7%), results also showed that respondents who were male were 16 respondents (35.6%) and women were 29 respondents (64.4%). The majority of respondents' educational backgrounds appear in this study were Primary and secondary education (Elementary, junior high

school, Senior High School) with 24 respondents (53.3%). The majority of the working status of respondents in this study did not work with 28 respondents (62.2%). The majority of respondents' knowledge in this study was good with 27 respondents (60%). The results showed that respondents who had no anxiety 15 respondents (33.3%), respondents with mild anxiety level 12 respondents (26.7%), respondents with moderate anxiety level 12 respondents (26.7%) and respondents with severe anxiety levels six respondents (13.3%). There was no relationship between age and sex with anxiety in hypertensive patients. There is a relationship between education, work, and knowledge with anxiety hypertension patients.

The next researcher can multiply new variables that have not been studied in this study to find out which factors are the dominant factors causing anxiety in hypertensive patients who are undergoing treatment. Anxiety is directly related to an increase in blood pressure so that someone needs to do counseling related to his condition to reduce anxiety, and need changes from individuals to change the risk factors for hypertension with healthy lifestyles such as fruit, vegetables, exercise regularly and reduce excessive consumption of calories and
